

Protocol 4: DNA isolation from frozen tissue with DNeasy procedure

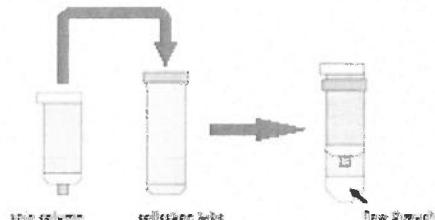

Best results are obtained with fresh material or material that has been immediately frozen and stored at -80°C. Repeated freezing and thawing of stored samples should be avoided, since this leads to reduced DNA size. In order to obtain optimum DNA yield and quality, it is important not to overload the DNeasy procedure, as this can lead to significantly lower yields than expected. Maximum amount of starting material of animal tissue is 25 mg. Cut off, if possible, contaminating normal tissue and pieces like necrosis. DNA isolation is performed with DNeasy Tissue Kit from Qiagen, art.nr. 69504. stored at RT. Buffers ATL and AL may form precipitates upon storage. If a precipitate has formed in either buffer, incubate at 55°C until the precipitate has fully dissolved. Buffers AW1 and AW2 are supplied as concentrates. Before using for the first time, add the appropriate amounts of abs. ethanol as indicated on the bottles.

Solutions:

- Buffers ATL, AL, AW1, AW2, AE -> buffers DNeasy-kit
- Prot k (10 mg/ml)
- RNAase A (10 mg/ml)
- EtOH_{abs}

Material:

- Eppendorf tubes (1,5 and 2,0 ml)
- DNeasy spin column, kit
- Thermal incubator, 55°C/70°C

Protocol:

- Cut up to 25 mg tissue and transfer it to a clean, sterile 2ml tube
- To lyse add 360 µl of buffer ATL
- Add 40 µl proteinase k and mix by vortexing
- Incubate at 55°C until the tissue is completely lysed; depending on type of tissue, usually 1-3 hours. Can be done overnight at 37°C.
- Optional: add 4 µl of RNase A, mix by vortexing and incubate for 2 min at room temperature
- Vortex for 15 seconds
- Add 400 µl of buffer AL to the sample, mix thoroughly by vortexing and incubate at 70°C
- Add 400 µl of EtOH_{abs} to the sample to bind the DNA to the DNeasy membrane and mix well
- Pipet 600 µl of the mixture into the DNeasy spin column
- Centrifuge 1 min at 8.000 rpm
- Discard flow-through
- Pipet remaining mixture (max 600 µl) into the column
- Centrifuge 1 min at 8.000 rpm
- Discard flow-through and collection tube
- Place the DNeasy spin column in a new 2 ml collection tube
- Add 500 µl of AW1 to the column
- Centrifuge 1 min at 8.000 rpm
- Discard flow-through and collection tube
- Place the DNeasy spin column in a new 2 ml collection tube
- Add 500 µl of AW2 to the column
- Centrifuge 3 min at full speed
- Discard flow-through and collection tube
- Place the DNeasy spin column in a new 2 ml collection tube
- Pipet 200 µl AE directly onto the DNeasy membrane
- Incubate at room temperature for 1 min
- Centrifuge for 1 min at 8.000 rpm to elute
- Pipet 100 µl of buffer AE directly onto the DNeasy membrane
- Incubate at room temperature for 1 min
- Centrifuge for 1 min at 8.000 rpm to elute
- Store DNA at 4°C or at -20°C if stored for a long time

Appendix 3: optimization DNA isolation from FFPE material

Because a substantial amount of 117 samples did not give results in the genotyping-SNP assays when using protocol 1 for DNA isolation, the integrity of the DNA was checked with an integrity PCR.

The principle of this PCR is as follows. In a mastermix 8 primers (4 pairs) are added. These primers produce products of different sizes: 100 basepairs (bp), 200 bp, 300 bp and 400 bp. If the integrity of the DNA is good all 4 products are made and can be visualized on a 1,5% agarose gel. If the quality of the DNA decreases, less bands are visible on the agarose gel. These results give an indication of the quality of the DNA.

The overall results of these PCR were that samples produced, no product, 100 bp and 200 bp in comparison with the pBl samples which show all 4 products. In figure A4-1 the results of pBl samples are shown on a 1,5% agarose gel.

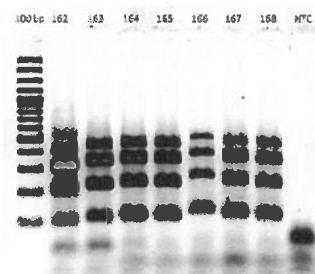

Figure A4-1: Integrity PCR; sample 162 until 168 are pBl samples showing all 4 product sizes.

The integrity of the samples, which did not give any results in the genotyping-SNP assays, were tested using this integrity PCR. In figure A4-2 these results are shown. Half of the samples did not give satisfactory results: 11 samples gave three or more bands, 12 samples gave zero to two bands.

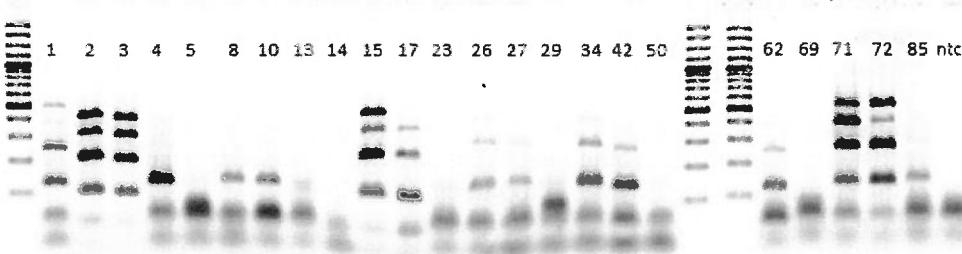

Figure A4-2: Integrity PCR

The conclusion was that the integrity of the DNA was not good enough to make products over 200 bp in size. This is probably because during fixation with formalin crosslinks are made and cannot be reversed with the current method. A new method was needed. After searching PubMed the following article was found.

Shi SR, Cote RJ, Wu L, Liu C, Datar R, Shi Y, Liu D, Lim H, Taylor CR. DNA extraction from archival formalin-fixed, paraffin-embedded tissue sections based on the antigen retrieval principle: heating under the influence of pH. J Histochem Cytochem 2002;50:1005-11.

This article used an isolation buffer which could reverse the crosslinks in the DNA with the help of a high pH and high temperature. The results of this article are shown in Figure A4-3.

In the article they looked at the yield, Figure A4-3: Figure 1, which was highest at pH 9. In Figure A4-3: Figure two a gel electrophoresis of PCR products is shown (152 bp, 347 bp and 541 bp). Actin the biggest product is produced when isolated at 100 °C and 120 °C with all different pH buffers. When lowering temperature only a buffer with a pH of 10 or higher shows a product. In Figure A4-3: Figure 3 the results of the "real time" PCR show that with a temperature of 120 °C and a pH of 11 most amplifiable DNA is produced.

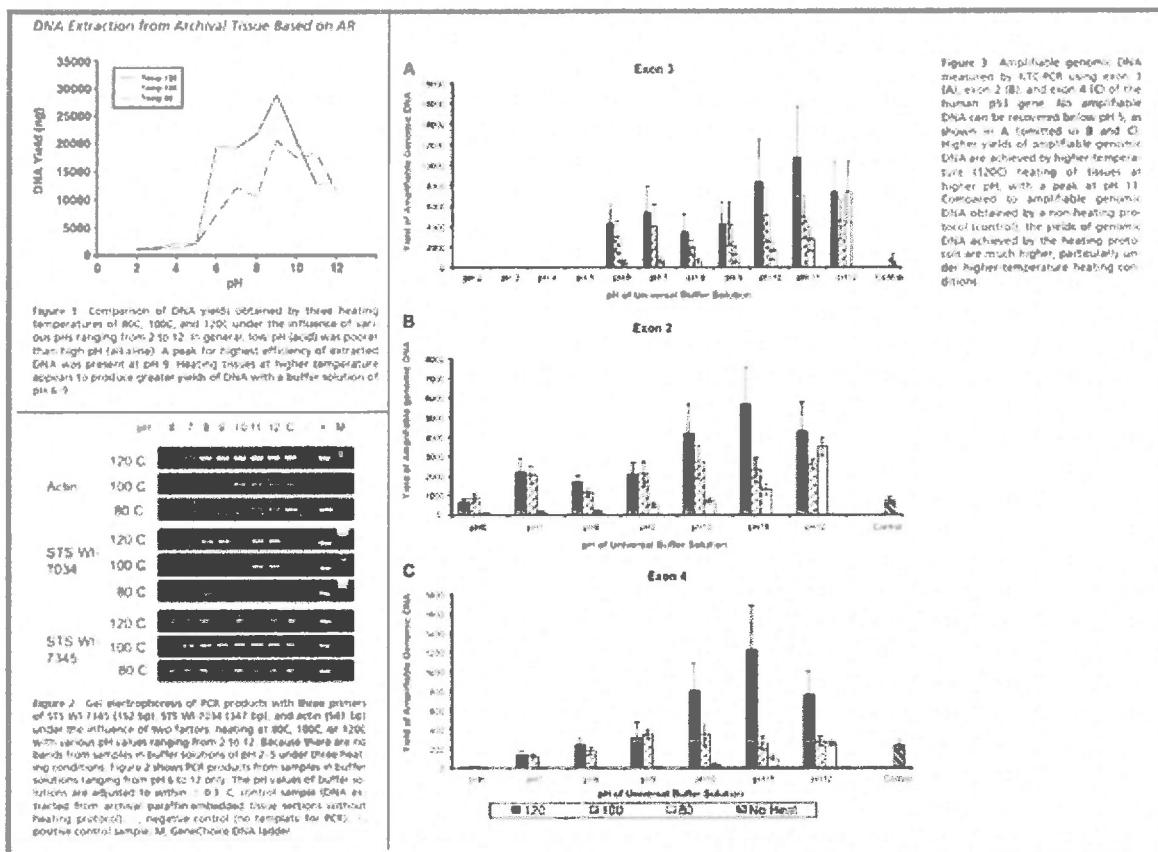

Figure A4-3 shows three figures shown in: DNA extraction from archival formalin-fixed, paraffin-embedded tissue sections based on the antigen retrieval principle: heating under the influence of pH.

With the results shown in Figure A4-3 an isolation buffer with a pH of 10 is made called universal buffer. At first this buffer was added to the tissue and the Eppendorf tube were put in the autoclave to reach a temperature of 120 °C. These results are shown in Figure A4-4.

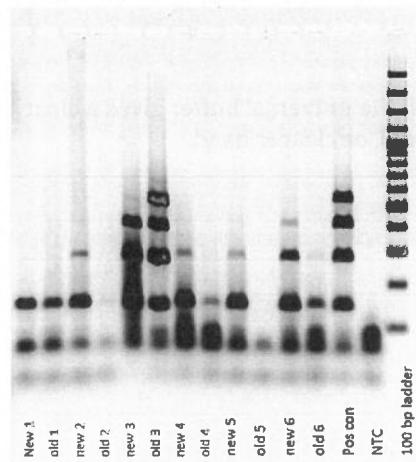

Figure A4-4: integrity PCR; 6 different samples (numbered 1 till 6) were used with protocol 1 (old) and with the new protocol, with the isolation step using the universal buffer pH 10 at 120 °C. 4 of the 6 samples show improvement using the new protocol. Sample 3 shows no improvement. Sample 1 says equal. Sample 1: 4, Sample 2: 8, sample 3: 9. Sample 4: 122, sample 5: 149, sample 6: 160.

Due to technical issues during this step. As an alternative it was chosen to use a heat block and a temperature of 100 °C could be reached.

For further optimization four conditions were tested. This was performed on one sample. Although pBl was available it did not give any results. For this experiment DNA from FFPE material was isolated using these four conditions .

1. Protocol 1, lysis buffer + prot K o.n. 52°C
2. New protocol, universal buffer, o.n. -20 °C
3. New protocol, universal buffer, o.n. 52°C lysisbuffer + prot K
4. New protocol, universal buffer, o.n. 52°C prot K

The results are shown in Figure A4-5. For the positive control a pBl sample is used shown A4-1.

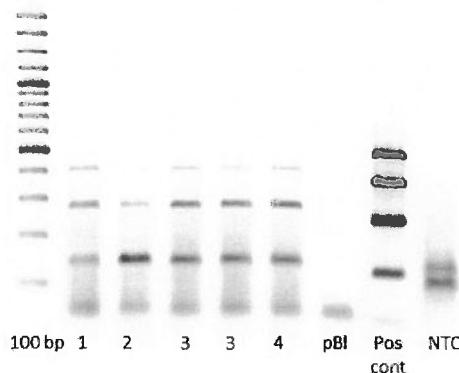

Figure A4-5: 4 isolation conditions and old pBl sample. Without o.n. step (2) less stronger band is shown. 1, 3 and 4 show similar results. pBl gave no bands.

From these results it was concluded that an o.n. incubation with prot K improved DNA quality. In a next step two conditions were tested on two samples (no 23 and 50) which showed zero product sizes in the quality control PCR. This was done because the first condition showed already three 3 bands in the previously used sample. The conditions chosen were:

1. New protocol, universal buffer, o.n. -20 °C
2. New protocol, universal buffer, o.n. 52°C prot K

These results are shown in Figure A4-6. Showing that isolating with the universal buffer gives a clear improvement. And adding an o.n. step with prot K gives an additional, or clearer band.

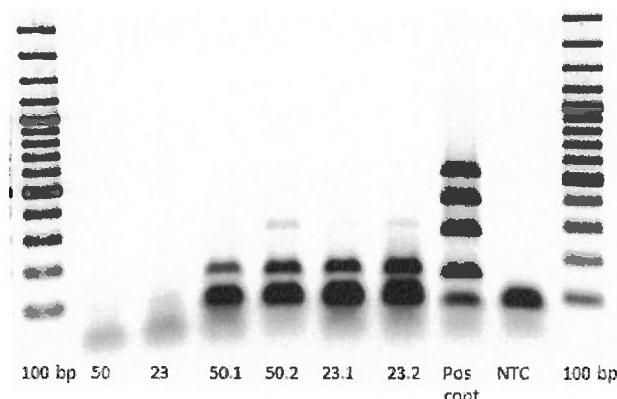

Figure A4-6: sample 50 and 23, isolated with protocol 1, 50.1 and 23.1 were isolated with universal buffer, 50.2 and 23.2 were isolated with universal buffer and adding prot K o.n. 52°C.

From 21 more samples DNA was isolated using the universal buffer with an o.n. step at 52 °C with prot K added. The DNA samples isolated with the old isolation (protocol 1) and the new protocol, were analyzed with the genotyping-SNP assays. If the DNA isolated using the old method already gave a result in the genotyping assay, it was not analyzed again on the DNA isolated with the new protocol from the same sample (indicated in grey). When a sample did not give a result, even after isolation with the new protocol, a red cross is placed in the table. When a sample gave an improvement in comparison with the old protocol the genotype is shown in green. When both samples were amplified, the sample isolated with this new protocol the amplification curve shifted towards left. Clearly an improvement can be seen using the new isolation method, this was further used as the standard isolation method for all FFPE samples (Appendix 2, protocol 2). See Table A4-1.

Isolation protocol using universal buffer on isolated samples

Protocol 2 optimized results on FFPE material. Seeing these improved results there might be a possibility that this isolation buffer could also improve the DNA quality of DNA isolated with isolation protocol 1. This was tested on five samples, using the four conditions given below. The results clearly show no improvement, see Figure A4-7. It is possible that the universal buffer with a high pH degraded the DNA.

1. Protocol 1
2. sample isolated with protocol 1, adding universal buffer o.n. at 52 °C
3. sample isolated with protocol 1, adding universal buffer 100 °C o.n. at 52 °C
4. protocol 2

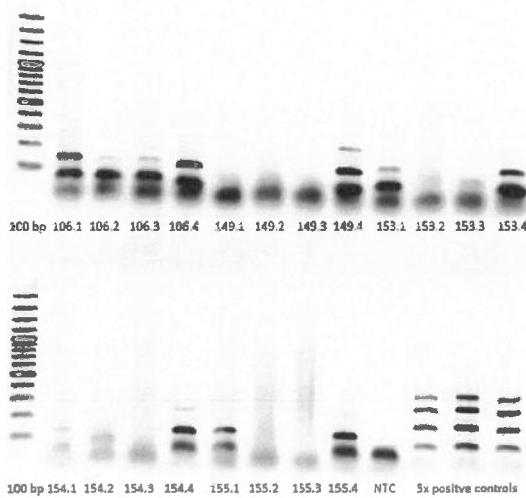

Figure A4-7: five different samples, four conditions. Condition two and three lose bands in comparison with condition one. Condition four improves in four of the five cases.

Table A4-1: overview protocol 1 (old) vs protocol 2 (new), protocol 2 shows a clear improvement in comparison with protocol 1.

Appendix 4: Taqman Genotyping Assay protocol

Before pipetting a plate setup is made. Depending on the amount of samples and assays a setup will be made using the guidelines below.

	1	2	3	4	5	6	7	8	9	10	11	12
A												
B												
C												
D												
E												
F												
G												
H												

Guidelines plate setup:

- 96-wells plate sorted by row, bottom right is reserved for the no-template control (NTC)
- Positive controls have to be positioned directly after the samples. (with 2 assays on a plate, first all samples are pipetted, after which the positive controls are added (assay 1 AA, BB, AB and then assay 2 AA, BB, AB)
- The NTC has to be always bottom right; so with two assays NTC 1 on H11 and NTC 2 on H12.
- With 2 assays on a plate use the same number of samples for both assays. Use the assay with the most samples designing a run, if the other assay has less samples leave wells open. This is necessary for the software to be able to run and analyze the results.

When the number of samples is known the amount of mastermix has to be calculated using the scheme below. Remember, make always 10% more mastermix than needed.

Scheme for pipetting the mastermix, per well 13 µl mastermix is pipetted.

<u>Mastermix:</u>			Number of samples	X
1x				
7,5 µL	PCR mastermix		...	µL
0,375 µL	SNP assay		...	µL
5,125 µL	dH2O		...	µL

The mastermix will be pipetted in a 96-wells plate using 13 µl per well, then 2 µl sample is added, with a concentration of 25 ng/µl. After pipetting a plate, the plate will be run on a AB 7500 Fast Real-Time PCR machine (ThermoFisher Scientific) according to the following program .

Temperature	time	Cycle
60.0°C	1 min	1
95.0°C	10 min	1
95.0°C	15 sec	45
60.0°C	1 min	
60.0°C	1 min	1

Appendix 6: raw data odd ratio rs4590952

In total this genotyping-SNP assay gave result for 644 patients in the TGCT group and for 230 patients in the 1000 genomes phase 3 EUR population. The allele frequency is shown below for both groups.

allele frequency TGCT group

	A	G
AA	14	0
AG	113	113
GG	0	1048
total	127	1161

allele frequency 1000 genomes EUR group

	A	G
AA	14	0
AG	66	66
GG	0	314
total	80	380

With this allele frequencies the OR is calculated in SPSS, the 2x2 table is shown below

2x2 table to calculate the OR

		TGCT		Total
		no	yes	
allele	A	94	127	221
	G	380	1161	1541
Total	474	1288	1762	

cross tabulation to calculate Chi-square, included CT

		allele		
		A	G	Total
TGCT	NS	59	523	582
	SE	60	704	764
Total		119	1227	1346

In Table 9 the data of the Chi-square test is shown, CT excluded. The p-value of the Chi-square test is 0.792 (2-sided). So in both analyses there is no significant difference in allele frequencies between SE and NS.

cross tabulation to calculate Chi-square, excluded CT

		allele		
		A	G	Total
TGCT	NS	38	472	510
	SE	60	704	764
Total		98	1176	1274
